

SOS Methods for Delay-Dependent Stability of Neutral Differential Systems

Matthew M. Peet, Catherine Bonnet and Hitay Özbay†*

1 Introduction

In this paper, we consider the problem of verification of certain frequency-domain tests for stability of delay systems of the neutral type. We show that several frequency-domain conditions can be reduced to optimization problems on the cone of positive semidefinite matrices. Such an approach is an alternative to the classical graphical tests (e.g. the Nyquist criterion). The motivation for using optimization-based methods is as follows

- a) The computational complexity of these methods is well-established. Computational complexity provides a standard benchmark for the difficulty of a given problem. A condition which is expressed as an optimization problem, therefore, will have well-known computational properties.
- b) While the accuracy of a result based on graphical methods may be limited by the resolution and range of the plot, a feasible result from an optimization-based method serves as a readily verifiable certificate of stability.

The use of frequency domain criteria for analysis of linear systems has an extensive history and we will not make an attempt to catalogue the list of accomplishments

†H. Özbay is with the Department of Electrical and Electronics Engineering, Bilkent University, Bilkent, 06800 Ankara, Turkey hitay@bilkent.edu.tr.

in this field. We do note, however, that while for finite-dimensional systems, time-domain-based LMI methods currently compete successfully with frequency-domain-based graphical criteria, the same can not be said to be true for infinite-dimensional systems.

In [2], we have already considered some simple delay-independent stability conditions for systems of the neutral type using SOS techniques. Our aim here is to develop more sophisticated methods which will allow us to check the delay-dependant H_∞ -stability of neutral systems. The paper is organized as follows. We begin in section 2 by recalling some background on polynomial optimization and “sum-of-squares”.

In section 3, we show how a method based on dichotomy arguments which was proposed by Zhang *et al* [10] for the stability analysis of retarded-type delay systems can also be applied to the case of neutral-type systems. The main theorems which enable us to formulate delay-dependant stability in terms of feasibility of semi-algebraic sets and SOS polynomials conditions are given. It is shown that the problem of the appearance of asymptotic chains of roots, common for neutral systems, is solved by the Zhang method of rational over-approximation. In Section 4 we give some numerical examples which show the efficacy of the proposed method. Finally a conclusion is given in section 5.

2 The Positivstellensatz and Sum-of-Squares

A polynomial, p , is said to be *positive* on $G \subset \mathbb{R}^n$ if

$$p(x) \geq 0 \quad \text{for all } x \in G.$$

If G is not mentioned, then it is assumed $G = \mathbb{R}^n$. A *semialgebraic set* is a subset of \mathbb{R}^n defined by polynomials p_i , as

$$G := \{x \in \mathbb{R}^n : p_i(x) \geq 0, i = 1, \dots, k\}.$$

Given a polynomial, the question of whether it is positive has been shown to be NP-hard. A polynomial, p , is said to be sum-of-squares (SOS) in variables x , denoted $p \in \Sigma_s[x]$ if there exist a finite number of other polynomials, g_i such that

$$p(x) = \sum_{i=1}^k g_i(x)^2.$$

A sum-of-squares polynomial is positive, but a positive polynomial may not be sum-of-squares. A necessary and sufficient condition for the existence of a sum-of-squares representation for a polynomial, p , of degree $2d$ is the existence of a positive semidefinite matrix, Q , such that

$$p(x) = Z(x)^T Q Z(x),$$

where Z is any vector whose elements form a basis for the polynomials of degree d . Positivstellensatz results are “theorems of the alternative” which say that either a

semialgebraic set is feasible or there exists a sum-of-squares refutation of feasibility. The Positivstellensatz that we use in this paper is that given by Stengle [9].

Theorem 1 (Stengle). *The following are equivalent*

1.

$$\left\{ x : \begin{array}{ll} p_i(x) \geq 0 & i = 1, \dots, k \\ q_j(x) = 0 & j = 1, \dots, m \end{array} \right\} = \emptyset$$

2. *There exist $t_i \in \mathbb{R}[x]$, $s_i, r_{ij}, \dots \in \Sigma_s[x]$ such that*

$$-1 = \sum_i q_i t_i + s_0 + \sum_i s_i p_i + \sum_{i \neq j} r_{ij} p_i p_j + \dots$$

We use $\mathbb{R}[x]$ to denote the real-valued polynomials in variables x . For a given degree bound, the conditions associated with Stengle's Positivstellensatz can be represented as a semidefinite program. Note that, in general, no such upper bound on the degree bound will be known a-priori.

3 Stability of Neutral-Type Systems

In this section we consider aspects of the stability of general neutral-type systems of the form

$$\dot{x}(t) = \sum_{i=1}^m B_i \dot{x}(t - \tau_i) + \sum_{j=0}^m A_j x(t - \tau_j) \quad (1)$$

where $A_i, B_j \in \mathbb{R}^{n \times n}$, $\tau_0 = 0$ and $\tau_i \geq 0$.

3.1 Dichotomy Methods

The term *dichotomy* is used to describe methods based on the bisection of the complex plane into right and left half-planes. These methods are based on a continuity argument that states that if a system is stable for one value of a parameter and unstable for another value, then for some intermediate value of the parameter, the system must have a pole on the imaginary axis. For retarded and for neutral-type systems which satisfy certain conditions, this argument is valid due to the following theorem from Datko [3]. Let

$$G_\alpha(s) := \left[s \left(I - \sum_{i=1}^m B_i e^{-\alpha s \tau_i} \right) - \sum_{j=0}^m A_j e^{-\alpha s \tau_j} \right]. \quad (2)$$

Theorem 2 (Datko). *Consider G_α as given by Equation (2). If*

$$\det \left[I - \sum_{i=1}^m B_i e^{-s \tau_i} \right] = 0$$

has all roots lying in some left half-plane $\operatorname{Re} s \in (-\infty, -\beta_0]$, $\beta_0 > 0$, then

$$\sigma(G_\alpha) := \sup_{\det G_\alpha(s)=0} \operatorname{Re} s$$

is continuous on $\alpha \in [0, \infty)$.

In general, a system of the form 1 will define a transfer function. The poles of this transfer function will be defined by the roots of $\det G(s) := \sum_{i=0}^n q_i(s)e^{-\tau_i s}$ where G_α is given by Equation (2). Here the q_i are complex polynomials with $\deg q_0 \geq \deg q_i$ for $i = 1, \dots, n$. In general, for neutral-type systems, $\deg q_0 = \deg q_i$ for at least one $i \geq 1$.

3.2 Generalization of a method of Zhang et al.

In this subsection, we consider the approach of [10], wherein the exponential term is “covered” by a set of rational transfer functions parameterized by a single parameter. The size of the set, or the range of values of the parameter, is determined by the degree of the rational functions. We begin with the definition of the Padé approximate of e^{-s} .

$$R_m(s) = \frac{P_m(s)}{P_m(-s)}$$

where

$$P_m(s) = \sum_{k=0}^m \frac{(2m-k)!m!(-s)^k}{(2m)!k!(m-k)!}.$$

Now define the sets of irrational and rational functions.

$$\Omega_d(\omega, h) := \{e^{-\iota\tau\omega} : \tau \in [0, h]\}$$

$$\Omega_m(\omega, h) := \{R_m(\iota\alpha_m\tau\omega) : \tau \in [0, h]\}$$

Where $\alpha_m := \frac{1}{2\pi} \min\{\omega > 0 \mid R_m(\iota\omega) = 1\}$. For example, $\alpha_3 = 1.2329$, $\alpha_4 = 1.0315$, and $\alpha_5 = 1.00363$.

The following is a key result of [10].

Lemma 3 (Zhang et al.). *For every integer $m \geq 3$, the following statements hold.*

1. All poles of $R_m(s)$ are in the open left half complex plane.
2. $\Omega_d(\omega, h) \subset \Omega_m(\omega, h)$ for any $h \geq 0$ and $\omega \geq 0$.
3. $\lim_{m \rightarrow \infty} \alpha_m = 0$

Typically, Lemma 3 is used to prove that a delay-differential system has no poles in the closed right half-plane for an interval of delay of the form $[0, h]$. This is illustrated by the following theorem.

Theorem 4. Suppose G , as given by Equation (2), satisfies the conditions of Theorem 2 and $\det G(s) := \sum_{i=0}^n q_i(s)e^{-\tau_i s}$. Let $m \geq 3$, and suppose that

$$\{s \in \mathcal{C} : \sum_{i=0}^n q_i(s) = 0, \operatorname{Re} s \geq 0\} = \emptyset$$

and

$$\{\omega \geq 0, \tau_i \in [0, h_i] : \sum_{i=0}^n q_i(\omega \iota) R_m(\alpha_m \tau_i \omega \iota) = 0\} = \emptyset.$$

Then

$$\{s \in \mathcal{C}, \tau_i \in [0, h_i] : \sum_{i=0}^n q_i(s)e^{-\tau_i s} = 0, \operatorname{Re} s \geq 0\} = \emptyset.$$

Theorem 4 is a trivial generalization of the work of Zhang et al. [10] to neutral-type systems. For retarded-type systems, the work of [10] proposed the construction of a parameter-dependent state-space system. In a later work, [1] proposed the use of a generalized version of the KYP lemma to check the conditions associated with the retarded case through the construction of a perturbed singular system. In this paper, we use a “sum-of-squares” approach based on the application of the Positivstellensatz results described in Section 2.

For convenience, define the following functions.

$$g_r(\omega, \tau) := \operatorname{Re} \left(\sum_{i=0}^n q_i(\omega \iota) P_m(\alpha_m \tau_i \omega \iota) \prod_{\substack{j=0 \\ j \neq i}}^n P_m(-\alpha_m \tau_j \omega \iota) \right)$$

$$g_i(\omega, \tau) := \operatorname{Im} \left(\sum_{i=0}^n q_i(\omega \iota) P_m(\alpha_m \tau_i \omega \iota) \prod_{\substack{j=0 \\ j \neq i}}^n P_m(-\alpha_m \tau_j \omega \iota) \right)$$

Lemma 5. The following are equivalent

1. The following set is infeasible.

$$\{\omega \geq 0, \tau_i \in [0, h_i] : \sum_{i=0}^n q_i(\omega \iota) R_m(\alpha_m \tau_i \omega \iota) = 0\}$$

2. The following real semi-algebraic set is infeasible.

$$\left\{ \omega, \tau_i \in \mathbb{R} : \omega \geq 0, \tau(h_i - \tau_i) \geq 0, g_r(\omega, \tau_i) = 0, g_i(\omega, \tau_i) = 0 \right\}$$

3. There exist polynomials $t_1, t_2 \in \mathbb{R}[\omega, \tau]$ and SOS polynomials $s_i \in \Sigma_s[\omega, \tau]$ such that

$$\begin{aligned} -1 = & s_0 + t_1 g_r + t_2 g_i + \omega s_1 + \tau_0 (h_0 - \tau_0) s_2 \\ & + \omega \tau_0 (h_0 - \tau_0) s_3 + \omega \tau_1 (h_1 - \tau_1) s_4 + \dots \end{aligned}$$

Proof. By Lemma 3, all roots of $P_m(-s)$ are in the open left half complex plane, and so Statement 1 is equivalent to infeasibility of the following set.

$$\left\{ \omega \geq 0, \tau_i \in [0, h_i] : \sum_{i=0}^n q_i(\omega \iota) P_m(\alpha_m \tau_i \omega \iota) \prod_{\substack{j=0 \\ j \neq i}}^n P_m(-\alpha_m \tau_j \omega \iota) = 0 \right\}$$

Now, $\tau \in [0, h]$ is equivalent to $\tau(h - \tau) \geq 0$ and so Statement 1 is equivalent to infeasibility of the set in Statement 2. Furthermore, the real or imaginary part of a complex polynomial is a polynomial in the real and complex parts of the complex argument. Therefore, the set in Statement 2 is real semi-algebraic.

That Statement 2 is equivalent to Statement 3 is an immediate consequence of Theorem 1. \square

We now give delay-dependent stability conditions for neutral-type systems.

Lemma 6. *Define*

$$r_m := \inf \left\{ \left\| \sum_{i=0}^n q_i(\omega \iota) R_m(\alpha_m \tau_i \omega \iota) \right\| : \omega \geq 0, \tau_i \in [0, h_i] \right\}$$

and

$$r_e := \inf \left\{ \left\| \sum_{i=0}^n q_i(\omega \iota) e^{-\tau_i \omega \iota} \right\| : \omega \geq 0, \tau_i \in [0, h_i] \right\}.$$

Then for any $m \geq 3$, $r_e \geq r_m$.

Proof. Suppose there exists an $\omega_w \geq 0$ and $\tau_{i,w} \in [0, h_i]$ such that

$$w = \left\| \sum_{i=0}^n q_i(\omega_w \iota) e^{-\tau_{i,w} \omega_w \iota} \right\|$$

Now, by Lemma 3, there exists $\tau'_{i,w} \in [0, h_i]$ such that

$$\left\| \sum_{i=0}^n q_i(\omega_w \iota) R_m(\alpha_m \tau'_{i,w} \omega_w \iota) \right\| = \left\| \sum_{i=0}^n q_i(\omega_w \iota) e^{-\tau_{i,w} \omega_w \iota} \right\| = w$$

Therefore, $r_m \leq w$ and hence $r_m \leq r_e$. \square

Theorem 7. *Suppose G_τ , given by Equation (2), satisfies the conditions of Theorem 2 and $\det G_\tau(s) := \sum_{i=0}^n q_i(s) e^{-\tau_i s}$. Let $m \geq 3$ and suppose that*

$$\{s \in \mathcal{C} : \sum_{i=0}^n q_i(s) = 0, \operatorname{Re} s \geq 0\} = \emptyset$$

and that there exist polynomials $t_1, t_2 \in \mathbb{R}[\omega, \tau]$ and SOS polynomials $s_i \in \Sigma_s[\omega, \tau]$ such that

$$\begin{aligned} -1 = & s_0 + t_1 g_r + t_2 g_i + \omega s_1 + \tau_1 (h_1 - \tau_1) s_2 \\ & + \omega \tau_1 (h_1 - \tau_1) s_3 + \omega \tau_2 (h_2 - \tau_2) s_4 + \dots \end{aligned}$$

Then the system defined by Equation 1 is H_∞ stable for all $\tau_i \in [0, h_i]$

Proof. If the conditions of the theorem are satisfied, then by Lemma 5

$$H_m(s) := \sum_{i=0}^n q_i(s) R_m(\alpha_m \tau_i s)$$

has no roots on the imaginary axis for any $\tau_i \in [0, h_i]$. Therefore, by Theorem 4 $\det G_\tau(s)$ has no roots on the closed right half plane. Therefore $\det G_\tau(s)^{-1}$ is analytic on the closed right half plane. It remains to show that $\det G_\tau(s)^{-1}$ is bounded on the imaginary axis.

Since H_m is a polynomial, then for any $\tau_i \in [0, h_i]$, it has a finite number of roots, none of which are on the imaginary axis. We conclude that for any fixed $\tau_i \in [0, h_i]$,

$$\inf_{\omega \geq 0} \left\| \sum_{i=0}^n q_i(\omega \iota) R_m(\alpha_m \tau_i \omega \iota) \right\| > 0$$

Therefore, since the $[0, h_i]$ are compact sets,

$$r_m := \inf \left\{ \left\| \sum_{i=0}^n q_i(\omega \iota) R_m(\alpha_m \tau_i \omega \iota) \right\| : \omega \geq 0, \tau_i \in [0, h_i] \right\} > 0.$$

Therefore, by Lemma 6,

$$r_e := \inf \left\{ \left\| \sum_{i=0}^n q_i(\omega \iota) e^{-\tau_i \omega \iota} \right\| : \omega \geq 0, \tau_i \in [0, h_i] \right\} \geq r_m > 0.$$

This proves that

$$\| \det G_\tau^{-1} \|_\infty = \sup_{\omega \geq 0} \| \det G_\tau(i\omega) \|^{-1} \leq \frac{1}{r_m}$$

and so $\det G_\tau(s)^{-1} \in H_\infty$ for any $\tau_i \in [0, h_i]$. \square

3.3 Delay-Independent Stability

To check stability independent of delay, the conditions of Theorem 7 may be modified slightly by considering the semialgebraic set

$$\left\{ \omega, \tau_i \in \mathbb{R} : \omega \geq 0, \tau_i \geq 0, g_r(\omega, \tau_i) = 0, g_i(\omega, \tau_i) = 0 \right\}.$$

In this section, we propose an alternative approach which eliminates the need for potentially high-order rational approximations. We begin by noting the following proposition which gives conditions that, when combined with the results of Datko, can be used to prove that no poles enter the right half-plane for any value of delay.

Proposition 1. *The following conditions are equivalent*

- The set $\{\omega \in \mathbb{R}, \tau \in \mathbb{R}^k : \omega \neq 0, \tau_k \geq 0 \text{ for } k = 1, \dots, n, \sum_{k=0}^n q_k(i\omega)e^{-i\omega\tau_k} = 0\}$ is empty.
- The set $\{\omega \in \mathbb{R}, \tau \in \mathbb{C}^k : \omega \neq 0, |z_k| = 1, \sum_{k=0}^n q_k(s)z_k = 0\}$ is empty.

Proof. We prove 2) \implies 1) by contrapositive. Suppose 1) is false for some ω_0, τ_k . Then let $z_k = e^{-\tau_k \omega_0 i}$, $\omega = \omega_0$, which is feasible for 2). Therefore, by contrapositive 2) \implies 1).

For 1) \implies 2), suppose 2) is false. Then there exists $\omega_0 \neq 0$ and $z \in \mathbb{C}^k$ with $|z_k| = 1$ such that $\sum_{k=0}^n q_k(i\omega_0)z_k = 0$. We can write $z_k = e^{-ia_k}$ with sign $a_k = \text{sign } \omega_0$. Let $\tau_k = \frac{a_k}{\omega_0}$ and $\omega = \omega_0$. Then we get

$$\sum_{k=0}^n q_k(i\omega)e^{-i\omega\tau_k} = \sum_{k=0}^n q_k(i\omega_0)e^{-i\omega_0\tau_k} = \sum_{k=0}^n q_k(i\omega_0)e^{-ia_k} = \sum_{k=0}^n q_k(i\omega_0)z_k = 0.$$

This contradicts 1) and completes the proof. \square

Proposition 1 is incomplete in that it does not prove H_∞ or exponential stability. This is because neutral-type delay systems can have infinite roots which may approach the imaginary axis, creating an unbounded high frequency response. This problem was avoided in the previous section by using rational approximations. To deal with this issue, we consider the case of commensurate delays. This is made explicit by the following Lemma.

Lemma 2. *The following conditions are equivalent*

1. The set $\{s \in i\mathbb{R}^+, \tau_k \in \mathbb{R}^+ : \sum_{k=0}^n q_k(s)e^{-sk\tau} = 0\}$ is empty.
2. The following semialgebraic set is empty

$$\left\{ \omega, z_i, z_r \in \mathbb{R} : 1 - z_i^2 + z_r^2 = 0, \quad \text{Re} \left(\sum_{k=0}^n q_k(i\omega)(z_r + iz_i)^k \right) = 0, \right. \\ \left. \text{Im} \left(\sum_{k=0}^n q_k(i\omega)(z_r + iz_i)^k \right) = 0 \right\}$$

3. There exist polynomials $t_1, t_2, t_3 \in \mathbb{R}[\omega, z_r, z_i]$ and $s \in \Sigma_s$ such that

$$\begin{aligned} -1 &= (z_r^2 + z_i^2 - 1)t_1 - \operatorname{Re} \left(\sum_{k=0}^n q_k(i\omega)(z_r + iz_i)^k \right) t_2 \\ &+ \operatorname{Im} \left(\sum_{k=0}^n q_k(i\omega)(z_r + iz_i)^k \right) t_3 + s. \end{aligned} \quad (3)$$

The proof is an application of Theorem 1. This leads to a simple condition for stability of neutral systems with commensurate delays.

Theorem 8. Suppose G_τ , as given by Equation (2), satisfies the conditions of Theorem 2 and $\det G_\tau(s) := \sum_{k=0}^n q_k(s)e^{-k\tau s}$. Suppose that

$$\{s \in \mathcal{C} : \sum_{i=0}^n q_i(s) = 0, \operatorname{Re} s \geq 0\} = \emptyset$$

and that there exist polynomials $t_1, t_2, t_3 \in \mathbb{R}[\omega, z_r, z_i]$ and $s \in \Sigma_s$ such that

$$\begin{aligned} -1 &= (z_r^2 + z_i^2 - 1)t_1 - \operatorname{Re} \left(\sum_{k=0}^n q_k(i\omega)(z_r + iz_i)^k \right) t_2 \\ &+ \operatorname{Im} \left(\sum_{k=0}^n q_k(i\omega)(z_r + iz_i)^k \right) t_3 + s. \end{aligned} \quad (4)$$

Then the system defined by Equation 1 is both H_∞ and exponentially stable for all $\tau \geq 0$

Proof. The proof is similar to that of Theorem 7. By combining Theorem 2, Lemma 2, and the assumption, G_τ has no roots on the imaginary axis for any positive value of τ . Moreover, for the case of commensurate delays, it can be shown that the conditions of Theorem 2 imply that a lack of roots in the closed right half-plane implies both exponential and H_∞ stability. \square

3.4 Verifying the Datko Conditions

In this section, we briefly consider the problem of verifying the conditions associated with Theorem 2. In particular, we would like to show that

$$\det \left[I - \sum_{i=1}^m B_i e^{-s\gamma_i} \right] = 0$$

has all roots lying in some left half-plane $\operatorname{Re} s \in (-\infty, -\beta_0]$, $\beta_0 > 0$.

A simple sufficient condition, also proposed in [3], is given by the following.

Proposition 9. Suppose $B_i = 0$ for $i = 1, \dots, m-1$ and $\det(\lambda I - B_m)$ has all roots in the disc $|\lambda| < 1$. Then the conditions of Theorem 2 are satisfied.

More generally, if the delays are commensurate, then the condition is equivalent to exponential stability of an expanded discrete-time linear system of the general form

$$\begin{bmatrix} x_1(k+1) \\ \vdots \\ x_n(k+1) \end{bmatrix} = \begin{bmatrix} B_1 & \dots & B_n \\ I & & \\ & I & \end{bmatrix} \begin{bmatrix} x_1(k) \\ \vdots \\ x_n(k) \end{bmatrix}.$$

If the delays are non-commensurate, then an SOS condition can also be given.

Lemma 10. Let $\epsilon > 0$. If

$$\left\{ z_i \in \mathbb{C} : \det \left(I + \sum_{i=1}^m B_i z_i \right) = 0, |z_i| \leq e^{\epsilon T_i} \right\} = \emptyset,$$

then

$$\det \left[I + \sum_{i=1}^m B_i e^{-s \gamma_i} \right] = 0$$

has all roots in the left half-plane $\{\operatorname{Re} s \leq -\epsilon\}$ for all $\gamma_i \leq T_i$.

Proof. Proof by contradiction. Suppose that there exist $(\gamma_1, \dots, \gamma_n) \in \mathbb{R}^n$ with $\gamma_i \leq T_i$ for $i = 1, \dots, m$ and $s_0 \in \{\operatorname{Re} s \geq -\epsilon\}$ such that

$$\det \left(I + \sum_{i=1}^m B_i e^{-\gamma_i s_0} \right) = 0.$$

Let $s = s_0$ and $z_i = e^{-\gamma_i s_0}$. Then $s_0 \in \{\operatorname{Re} s \geq -\epsilon\}$ and $|z_i| \leq e^{\epsilon T_i}$ with

$$\det \left(I + \sum_{i=1}^n B_i z_i \right) = 0,$$

which contradicts the statement of the lemma. \square

The conditions of Lemma 10 can be verified using SOS by application of Theorem 1.

4 Numerical Example

. **Example 1:** In this example, we consider a somewhat arbitrarily chosen example to illustrate the delay-dependent stability condition associated with Theorem 7. We use the example chosen by [4], [6], and [5] among many others.

$$\dot{x}(t) - B\dot{x}(t - \tau) = A_0 x(t) + A_1 x(t - \tau)$$

Table 1. *Stability Regions*

	$m = 3$	$m = 4$	$m = 5$	actual value
maximum τ	1.805	2.157	2.217	2.2255
required degree	14	18	22	

where

$$A_0 = \begin{bmatrix} -0.9 & 0.2 \\ 0.1 & -0.9 \end{bmatrix}, \quad A_1 = \begin{bmatrix} -1.1 & -0.2 \\ -0.1 & -1.1 \end{bmatrix}, \quad B = \begin{bmatrix} -0.2 & 0 \\ 0.2 & -0.1 \end{bmatrix}.$$

To test stability, we first verify the Datko conditions, which hold by Proposition 9. We now replace the characteristic equation

$$g(s) = \det(sI - A_0 - A_1 e^{-\tau s} - B s e^{-\tau s})$$

with the family of rational approximations R_m to get a new characteristic polynomial family

$$H_m(s, \tau) = \det \left(s P_m(-\alpha_m \tau s) I - A_0 P_m(-\alpha_m \tau s) - A_1 P_m(\alpha_m \tau s) - B s P_m(\alpha_m \tau s) \right)$$

We then create the real polynomial functions

$$g_i(\omega, \tau) := \operatorname{Re} H_m(i\omega, \tau) \quad \text{and} \quad g_r(\omega, \tau) := \operatorname{Re} H_m(\omega, \tau).$$

This can be done automatically in Matlab using the function `cpoly2rpoly` contained in the software package available online at [8].

We now use SOSTOOLS [7] to find polynomials $t_1, t_2 \in \mathbb{R}[\omega, \tau]$ and SOS polynomials $s_i \in \Sigma_s[\omega, \tau]$ for $i = 0, \dots, 3$ such that

$$-1 = s_0 + t_1 g_r + t_2 g_i + \omega s_1 + \tau(h - \tau)s_2 + \omega\tau(h - \tau)s_3$$

By using this method, we are able to prove stability of the system for the values of delay listed in Table 1. This table also lists the degree of the refutation necessary. The accuracy is roughly comparable to what is currently available using existing time-domain methods. Note that the accuracy is restricted only by the value of α_m .

5 Conclusion

We have proposed a method to check delay-dependant stability of neutral-type delay systems which involves the Padé approximate of e^{-s} and uses sum-of-squares methods to prove the infeasibility of certain semi-algebraic sets. The method is applied to a standard example from the literature.
